Probability law of the connectivity of the external vertices?

The Temperley–Lieb loop model ASM, FPL, 6v Classes of FPLs

The connectivity of the external vertices can be encoded into a link pattern = a planar pairing of 2n points on a circle.

Relation to Markov process on link patterns

Using a transfer matrix formalism, one can reformulate the computation of these probabilities in terms of a Markov process on link patterns (dependent on p):

Then the vector $|\Psi
angle=\sum_{\pi} Prob(\pi)|\pi
angle$ is the steady state eigenvector:

$$T(p)|\Psi\rangle = |\Psi\rangle$$

 Quantum Integrability of the loop model
 ASM, FPL, 6v

 First combinatorial properties
 The geometry

Denote by $A(\pi)$ the number of FPLs with connectivity described by the link pattern π . Razumov and Stroganov observed (2001), and then Cantini and Sportiello proved (2010), that $A(\pi)$ is exactly the (unnormalized) probability of pattern π in the model of loops with the geometry of the cylinder.

In other words $|\Psi\rangle = \sum_{\pi} A(\pi) |\pi\rangle$ is the (unnormalized) steady state of the Markov process of loops:

 ${\cal T}(
ho)|\Psi
angle=|\Psi
angle$

Remark: there are (still conjectural!) variations: other types of b.c. on TL \leftrightarrow different symmetry classes of ASM/FPL [Batchelor, de Gier & Nienhuis '01; Razumov-Stroganov '01; Pearce, de Gier & Rittenberg '01, ...]

イロト 不得 とくほ とくほ とうほう

Consider the probabilistic model (on the cylinder) with probabilities p_i depending on the column i = 1, ..., 2n, which we parameterize as $p_i = \frac{t-q z_i}{z_i-q t}$, $1-p_i = q^2 \frac{t-z_i}{z_i-q t}$, $q = e^{2\pi i/3}$.

This inhomogeneous model is still integrable, the z_i are the spectral parameters.

The corresponding steady state is $|\Psi(z_1, \ldots, z_{2n})\rangle$.

$$T(z_1,\ldots,z_{2n}|t)|\Psi(z_1,\ldots,z_{2n})\rangle = |\Psi(z_1,\ldots,z_{2n})\rangle$$

イロト イポト イヨト イヨト

Inhomogeneous TL model The qKZ equation Level 1 solution and loop model

• Polynomiality.

 $|\Psi(z_1,...,z_{2n})\rangle$ can be normalized in such a way that its components are homogenous polynomials of total degree n(n-1) and of partial degree at most n-1 in each z_i .

• Factorization and symmetry.

The components possess various linear factors and properties of symmetry by exchange of variables.

In particular, their sum is a symmetric polynomial of all z_i .

Recursion relations.

Components of $|\Psi(z_1, \ldots, z_{2n})\rangle$ satisfy linear recursion relations; their sum is entirely determined by these:

$$\sum_{\pi} \Psi_{\pi}(z_1, \ldots, z_{2n}) = IK_n(q; z_1, \ldots, z_{2n}) = Schur(\underline{\qquad}; z_1, \ldots, z_{2n})$$

Inhomogeneous TL model **The** *q***KZ equation** Level 1 solution and loop model

Motivation

The quantum Knizhnik–Zamolodchikov equation is a system of equations that appears:

- in the study of form factors of integrable models [Smirnov, '86]
- in the representation theory of quantum affine algebras [Frenkel, Reshetikhin '92]
- in the study of correlation functions of integrable models [Jimbo, Miwa et al, '93]
- in relation to representation theory of affine Hecke algebra and DAHA [Cherednik, Pasquier, '90s]
- As we shall see now, it can also be applied to the Temperley–Lieb loop model [Di Francesco, PZJ, '05]

Inhomogeneous TL model **The** *q***KZ equation** Level 1 solution and loop model

The Temperley–Lieb algebra

The Temperley–Lieb algebra $TL_L(\tau)$ (a quotient of the Hecke algebra) is defined by generators e_i , i = 1, ..., L - 1, and relations

$$e_i^2 = \tau e_i$$
 $e_i e_{i\pm 1} e_i = e_i$ $e_i e_j = e_j e_i$ $|i-j| > 1$

Define the action of Temperley–Lieb generators e_i on link patterns:

Inhomogeneous TL model **The** *q***KZ equation** Level 1 solution and loop model

Introduce the rotation operator ρ such that $\rho e_i \rho^{-1} = e_{i+1}$. This allows to define an extra element

$$\mathbf{e}_{L} = \rho \mathbf{e}_{L-1} \rho^{-1} = \rho^{-1} \mathbf{e}_{1} \rho$$

Together the e_1, \ldots, e_L form a representation of the *affine* Temperley–Lieb algebra.

ho naturally acts on link patterns by rotating them/shifting them cyclically:

Homogeneous limit for generic *q* Particular components Young diagrams and polynomiality

What is the combinatorial meaning of the level 1 polynomial solution of qKZ for generic q? In particular, what can one say about the homogeneous limit $z_i = 1$?

where $\tau = -q - q^{-1}$.

In general, one observes that the components are always polynomials of τ with non-negative integer coefficients.

Homogeneous limit for generic *q* Particular components Young diagrams and polynomiality

Polynomiality

For a given Young diagram λ , $\Psi_{\lambda,n}(\tau)$ is a polynomial of both nand τ , of degree $|\lambda|$ in both. [at $\tau = 1$, conjectured by Zuber and proven by Caselli, Krattenthaler, Lass, Nadeau for FPLs; for any τ , proven by Fonseca + Z-J]

In fact, the leading term in τ is known explicitly in terms of the subset s:

$$\Psi_{\lambda,n} \stackrel{\tau \to \infty}{\sim} \tau^{|\lambda|} \det \left[\binom{i-1}{\bar{s}_i - j} \right]_{i,j=1,\dots,n} = \tau^{|\lambda|} \det \left[\binom{n-i}{n-s_i + j} \right]_{i,j=1,\dots,n}$$

Homogeneous limit for generic *q* Particular components Young diagrams and polynomiality

Plücker relations and NILPs

Let us translate this into combinatorics.

Explicitly, Gr(b, b + c) can be written in terms of coordinates and equations. The coordinates are the Plücker coordinates p_s indexed by subsets s of $\{1, \ldots, b + c\}$ of cardinality b. The equations are certain quadratic relations called Plücker relations.

Example:

 $Gr(2,4) = \{ [p_{12}, p_{13}, p_{14}, p_{23}, p_{24}, p_{34}] : p_{12}p_{34} - p_{13}p_{24} + p_{14}p_{23} = 0 \}$

Theorem: a basis of global sections of the sheaf associated to the integers $a_r \ge 0$, r corner of λ , is given by associating to each tableau as above the product of Plücker coordinates associated to level curves of the tableau [and dividing by the appropriate power of p_{λ} itself].

General linear group action and character

The natural action of GL(2n) on Gr(n, 2n) restricts to an action of $\prod_k GL(|A_k|)$ on X^{λ} . This means global sections of any sheaf on X^{λ} carry a representation of $\prod_k GL(|A_k|)$ (up to an overall twist), and we can compute the character of the space of its global sections.

Combinatorially, pad reverse partitions with zeros above and $a = \max_r a_r$ below; then the character is given (up to an overall monomial) by

$$\sum_{RPP} \prod_{\alpha \in \mathcal{B}} z_{c(\alpha)+n}^{\beta-\alpha}$$

where $c(\Box) = column - row$.

Application

Now given a link pattern and its associated Young diagram, define a sheaf σ_{λ} by choosing integers to be the distance to the diagonal:

By application of the Lindström–Gessel–Viennot formula, we find that the number of global sections / reverse plane partitions is

$$\det\left[\binom{i-1}{\overline{s}_i-j}\right]_{i,j=1,\dots,n} = \det\left[\binom{n-i}{n-s_i+j}\right]_{i,j=1,\dots,n}$$

Application cont'd

The leading $\tau \to \infty/q \to 0$ term The full answer Gröbner degeneration

The equality of the number of global sections of σ_{λ} with the leading $\tau \to \infty$ behavior of $\Psi_{\lambda,n}$ is a strong indication that we're headed the right way.

Even better, the character of the space of global sections of σ_{λ} , coincides, as expected, with

$$\lim_{q\to 0} \Psi_{\lambda,n}(z_1,\ldots,z_{2n};q)$$

Remarks

- Link patterns (i.e., Young diagrams inside the triangle) are exactly the cases where all numbers are nonnegative.
- For any Young diagram in the n × n square, there is no higher sheaf cohomology ⇒ we are computing the pushforward to a point of σ_λ in K-theory.
- Polynomiality in *n* becomes obvious (pushforward to a point is always a polynomial of the overall shift of the integers).
- Fonseca and Nadeau consider " $\Psi_{\lambda,0}$ " which in our language would correspond to setting the integers as if the diagonal passed through the origin. Note that here the higher sheaf cohomology spaces finally kick in.

The extra circle action

Note that the variables z_i , i = 1, ..., 2n are the formal parameters associated to computing the character w.r.t. the Cartan torus $(\mathbb{C}^{\times})^{2n}$ of GL(2n) (or one of its subgroups $\prod_k GL(|A_k|)$).

In order to reintroduce the parameter q, it is natural to enhance our geometric setting to incorporate an extra circle \mathbb{C}^{\times} action.

Idea: replace X^{λ} with the total space of a vector bundle over X^{λ} :

$$\begin{array}{c} CX^{\lambda} \to X^{\lambda} \\ (x, \vec{v}) \mapsto x \end{array}$$

Then the extra action is scaling of the fiber, i.e., $(x, \vec{v}) \in CX^{\lambda} \mapsto (x, t \vec{v}).$

Digression: Hall-Littlewood polynomials

This extra circle action is standard in geometric representation theory.

In fact, if we extend the Borel–Weil construction, e.g., on Gr(b, b + c), by replacing Gr(b, b + c) with its cotangent bundle $T^*Gr(b, b + c)$, and then taking the same O(a) sheaf (obtained by pullback from Gr(b, b + c)), then the corresponding character would be nothing but the (dual) Hall–Littlewood polynomial (with Young diagram $c \times b$).

The leading $\tau \to \infty/q \to 0$ term The full answer Gröbner degeneration

Cotangent bundle of the Grassmannian

Here we do something different: we consider the cotangent bundle of the ambient space, that is Gr(n, 2n).

This cotangent bundle has a very simple explicit description:

 $T^*Gr(n,2n) = \left\{ (V,u) \in Gr(n,2n) \times \operatorname{End}(\mathbb{C}^{2n}) : \operatorname{Im} u \subset V \subset \operatorname{Ker} u \right\}$

(justification: the fiber of *TGr* at *V* lives in Hom($V, \mathbb{C}^{2n}/V$); so the dual fiber is Hom($\mathbb{C}^{2n}/V, V$) which is naturally a subspace of End(\mathbb{C}^{2n}) where $u|_V = 0 \Leftrightarrow V \subset \text{Ker } u$ and Im $u \subset V$.)

Relation to Okounkov theory

Okounkov et al define the *R*-matrix geometrically as a matrix of change of basis in the (localized, equivariant) *K*-theory ring $K_T^{loc}(T^*Gr(n, 2n))$; here implementing the natural Weyl group action (S_{2n}) on the ambient space $T^*Gr(n, 2n)$.

However this matrix depends (nontrivially!) on a choice of basis of this ring. The choice made here (certain sheaves on conormal Schubert varieties) produces the *R*-matrix of the Temperley–Lieb loop model (which was our starting point).

Okounkov prefers the use of the so-called stable basis, which leads to the *R*-matrix of the six-vertex model. However in the Grassmannian case, the change of basis is very easy (maximal parabolic Kazhdan–Lusztig polynomials), so that the corresponding integrable models are easily shown to be equivalent

(a, b, c) cont'd

The sheaf O(a) simply consists of polynomials in the p_s and the entries of B and C which are of degree a in the p_s (note that the degree in B and C is free, but incurs a weight of t in the computation of the character = generating/Hilbert series).

As before, one can eliminate the Plücker relations by considering only $\prod_{\alpha=1}^{a} p_{s_{\alpha}}$ where the s_{α} are in bijection with lozenge tilings. The dependence on B and C remains arbitrary, modulo the bilinar relations $bil(p_s, B_{ij}) = 0$ and $bil'(p_s, C_{ij}) = 0$.

(a, b, c) and Gröbner degeneration

Theorem (Knutson, Z-J, '16)

There exists a Gröbner degeneration of the space of global sections of σ_{λ} (where $\lambda = (a, b, c)$), such that the equations take the following form: For each monomial $\prod_{\alpha=1}^{a} p_{s_{\alpha}}$ and its associated lozenge tiling, the equations are

1

•
$$\prod_{\alpha=1}^{a} p_{s_{\alpha}} B_{ij} = 0$$
 for each lozenge \square at location (i, j) .

•
$$\prod_{\alpha=1}^{a} p_{s_{\alpha}} C_{jk} = 0$$
 for each lozenge \checkmark at location (j, k) .

•
$$\prod_{\alpha=1}^{a} p_{s_{\alpha}}(BC)_{ik} = 0$$
 for each lozenge \checkmark at location (i, k) .

(this is a slight simplification...equations above actually define toric varieties)

The leading $\tau \to \infty/q \to 0$ term The full answer Gröbner degeneration

Theorem (Knutson, Z-J, '16)

There exists a Gröbner degeneration of the space of global sections of σ_{λ} (where $\lambda = (a, b, c)$), such that the equations take the following form: For each monomial $\prod_{\alpha=1}^{a} p_{s_{\alpha}}$ and its associated lozenge tiling, the equations are

1

•
$$\prod_{\alpha=1}^{a} p_{s_{\alpha}} B_{ij} = 0$$
 for each lozenge at location (i, j) .

•
$$\prod_{\alpha=1}^{a} p_{s_{\alpha}} C_{jk} = 0$$
 for each lozenge \checkmark at location (j, k) .

•
$$\prod_{\alpha=1}^{a} p_{s_{\alpha}}(BC)_{ik} = 0$$
 for each lozenge \checkmark at location (i, k) .

(this is a slight simplification... equations above actually define toric varieties)

The leading $\tau \to \infty/q \to 0$ term The full answer Gröbner degeneration

Example cont'd: a = b = c = 1

The degenerated bilinear equations read

$$\begin{pmatrix} p_1 & p_2 \end{pmatrix} \begin{pmatrix} 0 & B_{22} & C_{11} & 0 \\ B_{11} & 0 & 0 & -C_{22} \end{pmatrix} = 0$$

which must be supplemented by the equations

$$p_1(BC)_{12} = 0, \qquad p_2(BC)_{21} = 0$$

These equations correspond to the two lozenge tilings

(a, b, c) and Gröbner degeneration cont'd

This immediately implies an explicit formula for Ψ_{λ} :

$$\begin{split} \Psi_{(a,b,c)} \propto & \sum_{\substack{\text{lozenge tilling of } PP(a,b,c) \\ \text{lozenges } (i,j) \\ \text{of type } B}} & \prod_{\substack{\text{lozenges } (i,k) \\ \text{of type } B}} & (1 - t \, z_i / z_{j+a+b}) \prod_{\substack{\text{lozenges } (j,k) \\ \text{of type } C}} & (1 - t \, z_{j+a+b} / z_{k+a+2b+c}) \\ \prod_{\substack{\text{lozenges } (j,k) \\ \text{of type } C}} & (1 - t \, z_{j+a+b} / z_{k+a+2b+c}) \\ \end{array} \end{split}$$

In particular, in the homogeneous limit $z_i = 1$, we immediately recover, noting $1 - t^2 = (1 - t)(1 + t) = -q^{-1/2}(1 - t)\tau$,

$$\Psi_{(a,b,c)}|_{homogeneous} = \tau^{bc}|PP(a,b,c)|$$

The leading $\tau \to \infty/q \to 0$ term The full answer Gröbner degeneration

(a, b, c) and Gröbner degeneration cont'd

This immediately implies an explicit formula for Ψ_{λ} :

$$\begin{split} \Psi_{(a,b,c)} \propto & \sum_{\substack{\text{lozenge tilling of } PP(a,b,c) \\ \text{lozenges } (i,j) \\ \text{of type } B}} & \prod_{\substack{\text{lozenges } (i,k) \\ \text{of type } B}} & (1 - t \, z_i / z_{j+a+b}) \prod_{\substack{\text{lozenges } (j,k) \\ \text{of type } C}} & (1 - t \, z_{j+a+b} / z_{k+a+2b+c}) \\ \prod_{\substack{\text{lozenges } (j,k) \\ \text{of type } C}} & (1 - t \, z_{j+a+b} / z_{k+a+2b+c}) \\ \end{array} \end{split}$$

In particular, in the homogeneous limit $z_i = 1$, we immediately recover, noting $1 - t^2 = (1 - t)(1 + t) = -q^{-1/2}(1 - t)\tau$,

$$|\Psi_{(a,b,c)}|_{homogeneous} = au^{bc} |PP(a,b,c)|$$

PDF's conjecture

The same strategy works for other series of examples. In fact, we recover this way more than the Razumov–Stroganov correspondence; we get a proof (for various series of examples) of

Conjecture (Di Francesco, '06)

For every link pattern $\pi,\,\Psi_\pi$ can be decomposed as a sum of products of the form

$$\Psi_{\pi} = \sum_{f \in FPL_{\pi}} \prod_{a=1}^{n(n-1)} \left(q^{\alpha_{f,a}} z_{j_{f,a}} - q^{-\alpha_{f,a}} z_{i_{f,a}} \right)$$

where $\alpha_{f,a} \in \{1,2\}$, and the indexing set FPL_{π} is the set of FPLs with connectivity π .

which itself implies positivity of coefficients of $\Psi_{\pi|homogeneous}(\tau)$.
